THE THEORY OF THE PARLAMENTUM ECONOMY

A complete tour of the game's economy — every formula, every flow, with worked simulations.

UPDATED 2026-10-10

Parlamentum's economy is built on one design law: **nothing is capped, but everything has a cost that grows with it.** Stats climb forever, companies level forever, you may work as many shifts as your energy allows — yet every curve bends, every output has a consumer, and every fortune leaks. This article walks the whole machine: the formulas as they run in the live game, and simulations showing what they mean in practice.

1. ENERGY — THE ACTION CURRENCY

Everything you do spends energy, and energy returns on a clock:

$$\text{regen} = 1 \text{ energy} \ / \ \text{minute} \quad (\approx 1440/\text{day})$$

$$\text{energyMax}(L) = \min(300,\ 100 + 5(L-1))$$

A work shift block costs **10 energy**; a war strike spends **all** your current energy in one blow (minimum 10; in a naval landing, whole 40-energy blocks). Food restores energy on top of regen — never above your maximum, and at most **10 units per UTC day** (**20** with Premium), which makes tier choice matter:

FOOD TIER	ENERGY/UNIT	MAX DAILY FROM FOOD	WITH PREMIUM
T1	10	100	200
T3	30	300	600
T5	50	**500**	**1,000**

Energy drinks are the only way to buy energy with gold: **1 gold = 10 drinks = 10 energy**, one use per 10 minutes, and a use fills exactly your missing energy. Money buys convenience, never a stat.

Regional Health infrastructure, a Conservative government (+25%) and a convoy Field Hospital speed the clock (section 8), stacking additively:

$$\text{tick interval} = \frac{60\text{s}}{\text{healthMult} + \text{convoyRegen}}$$

Golden Hours run every day from **17:00 to 18:00 UTC**. Inside the window energy regenerates twice as fast (only the minutes inside it count double), and work shifts and war strikes pay double XP. The daily reward and missions stay flat.

2. STATS AND TRAINING — TIME IS THE GATE

Three stats drive the economy: **Strength** (war damage), **Education** (training speed and production), **Economy skill** (production and wages). Training to stat level n costs n gold and takes:

$$t(n) = \text{round}\left(0.2894 \cdot n^{2.5} \cdot \frac{1}{1 + 0.01E}\right) \text{ seconds}$$

never less than one second. The $n^{2.5}$ term sets the pace: every point takes longer than the last, but there is no wall. Cumulative queue time (at $E = 0$):

TARGET STAT	SINGLE LEVEL	CUMULATIVE FROM 0
20	~9 min	~54 min
40	~49 min	~10 hours
50	~1.4 h	~21 hours
60	~2.2 h	~40 hours
70	~3.3 h	~2.8 days
100	~8 h	~10 days
200	~45 h	~109 days

Stats never cap — past ~200 each point is a project measured in days. A year of non-stop training, one stat at a time and Education first, brings all three stats to about **300**.

The time is then cut by the region's Education index (up to **−25%**, more in a Top 3 city), Liberalism (**−15%**), a convoy Field Academy (up to **−10%**) and Premium (**−10%**). The cuts are additive, and a training never drops below a tenth of its time. Only one stat trains at a time.

3. PRODUCTION — THE MASTER FORMULA

One work click converts your entire energy into goods:

$$\text{unitsPerBlock} = 2 \cdot M_{\text{stat}} \cdot M_{\text{company}} \cdot \left(1 + \tfrac{r}{100}\right)$$

$$M_{\text{stat}} = 1 + 0.02\,S_{\text{eco}} + 0.015\,E + 0.005\,(L - 1)$$

where r is the region resource bonus (only when the region's resource matches a Resource Plant's product). The regional Industry index (plus Socialism in the country that owns the region, and a convoy Mobile Workshop) then scales the block, and the region's work capacity adjusts it:

$$\text{ups} = \max\!\left(1,\ \text{unitsPerBlock} \cdot (M_{\text{industry}} + \text{ideology} + \text{convoyProd}) \cdot m_{\text{crowd}} \cdot m_{\text{pioneer}}\right)$$

$$\text{units produced} = \left\lfloor \tfrac{\text{energy} \cdot \text{ups} \cdot m_{\text{capital}}}{10} \right\rfloor$$

- m_{crowd} is 1 while the region's shared energy pool is at least half full, and slides toward **×0.5** as it empties.
- m_{pioneer} is up to **×1.10** in a region where few players are active (15 or fewer in the last 24 hours, fading out by 30).
- m_{capital} is **0.9** for 30 days after the company's country lost its capital in war.

Only the shift total is rounded down, so every bonus shows, however small. The shift charges only the energy its whole units needed; the remainder stays in your bar. Infrastructure & Region Capacity explains the energy pool and the pioneer bonus.

Company multipliers grow slowly and without cap:

$$M_{\text{RAW}}(n) = 1 + 0.01\,(n - 1) \qquad M_{\text{MFG}}(n) = Y_{\text{tier}} \cdot \big(1 + 0.02\,(n - 1)\big)$$

with tier yields $Y = 1.0/0.8/0.65/0.5/0.4$ for T1–T5: higher tiers yield fewer units per shift but each unit is worth far more. Factories, Light Industry (always at the T1 yield) and Shipyards use M_{MFG}; Resource Plants use M_{RAW}.

Because M_{stat} is linear and training has no wall, the gap between a newcomer and a veteran keeps growing — slowly. Economy 300, Education 300 and level 200, about a year of non-stop play, give $M_{\text{stat}} = 1 + 6 + 4.5 + 1 \approx 12.5$ against a newcomer's 1. The gap is real, but it is earned one day at a time.

4. THE SEVEN RAW MATERIALS

Every region carries one resource, and a Resource Plant producing that raw there earns the region's resource bonus. Any raw can be produced in any region; the bonus is the only difference. Each raw has its

own consumers:

RAW	CONSUMED BY
Grain	Food factories, every state building, closed borders
Iron	Weapon factories, Military Bases, Construction Materials
Oil	Ticket factories, every state building, Fuel, closed borders
Cotton	Field Hospitals, Hospitals and Schools, Electronics
Timber	Field Academies, Schools, Construction Materials
Coal	Mobile Workshops, Power Plants, Industrial Zones, Fuel
Copper	Forward Commands, Missile Systems, Electronics

Manufacturing burns raws per finished unit on a steep tier curve:

$$\text{rawPerUnit} = 10/20/35/60/100 \quad (T1 \dots T5)$$

Tickets are deliberately oil-hungry: $25/50/90/150/250$ oil per ticket. A T5 good therefore locks up **10×** the raw of a T1 — quality is the economy's built-in raw sink.

Light Industry turns **5 + 5** raws into one component: Construction Materials (iron + timber), Fuel (coal + oil) or Electronics (copper + cotton). A Shipyard turns components into ships (section 7). A plant with several inputs stops at the scarcest one.

5. COMPANIES, WAGES AND TAXES

Founding a Resource Plant or a Factory — any tier — costs a flat **100 gold**. Light Industry costs **250 gold**, and Heavy Industry (a Shipyard, coastal regions only) **500 gold**. Every company needs player **level 15** and is founded in your own country, in the region you stand in. Upgrading to level n costs $15n$ gold **and** production experience, which the upgrade spends:

$$\text{exp}_{\text{MFG}}(n) = \text{round}\big(275 \cdot (n-1)^{1.5} \cdot Y_{\text{tier}}\big) \qquad \text{exp}_{\text{RAW}}(n) = \text{round}\big(200 \cdot (n-1)^{1.5}\big)$$

The first curve is for Factories, Light Industry and Shipyards, the second for Resource Plants. A Resource Plant's upgrade to level n also burns **50 × n** units of its own output from the company's stock. Money alone cannot level a company — the grind cannot be skipped. Closing refunds half of the gold invested (the founding fee plus every upgrade). A company employs at most $\min(50, \text{level})$ workers. For **100 gold** a company can move to your citizenship region.

A worker's wage per 10-energy block:

$$w = w_{\text{base}} + \left\lfloor \frac{S_{\text{eco}} \cdot m}{100} \right\rfloor$$

recomputed from the worker's *current* skill each shift, then scaled by energy actually spent. A company can pay a share of the output instead of a wage — at least **10%**.

Income tax comes off the top of wages; production tax takes a share of **Resource Plant** output **in kind** into the state stockpile (every other company pays none); import and export taxes guard the global market. Every rate is capped at **50%** and changes through a **Set a tax rate** law — voted by parliament, or enacted directly by the president or the Economy Minister. Any positive amount of money taxed owes at least the smallest coin — there is no tax-free trickle — while the production tax simply rounds down.

6. MARKETS

- **Local market** — trades in the state currency; the seller's proceeds pay income tax.
- **Global market** — trades in gold across borders. The buyer pays the import tax of their country on top of the price, and the export tax of the seller's country comes off the seller's proceeds. A trade agreement between two countries zeroes the import tax both ways. A side without a country pays a flat **10%** **frontier levy** instead, and it is burned. Embargoes hide markets between hostile states.
- **FX** — player order book between gold and the ten currencies, plus a government desk where treasuries post standing gold rates. The **Mint** turns **1 gold into 10** units of any local currency, without limit — and only that way round: local currency never mints back into gold.

Charts track the **volume-weighted average price of executed trades** — offers can be withdrawn, trades cannot.

7. THE WAR ECONOMY

War is the economy's furnace. A strike spends all energy and burns weapons scaled by your level:

$$\text{weaponsPerBlock} = 1 + \lfloor L/8 \rfloor$$

$$\text{damage} = \text{weapons} \cdot (5 + S_{\text{str}}) \cdot Y_w \cdot \left(M_{\text{military}} + \text{convoyDmg}\right) \cdot m_{\text{capital}}$$

with weapon tier multipliers $Y_w = 1.0/1.5/2.0/2.5/3.0$. M_{military} is the front region's Military index bonus plus Nationalism in the country that owns that region; m_{capital} is 0.9 for 30 days after your own country lost its capital. The result is then rolled — a uniform swing of $\pm 10\%$ and a 5% chance of a critical at $\times 1.5$ — and only then rounded down, never below 1: variance the individual feels and the war-long total

barely notices. If you hold too few weapons for your whole bar, the strike spends only the energy your weapons cover.

War pays **20 XP per 10 energy** — five times the work rate, doubled again in Golden Hours — making it the fastest ladder and the deepest sink at once: a high-level fighter can burn through several producers' daily output in a single war day. A war lasts **24 hours** and a tie goes to the defender. The losing side's region then loses between 10% and 50% of each kind of building: the closer the war, the heavier the damage.

Ships and the naval landing. The production chain runs one stage deeper for the sea: raws → components (Light Industry, 5 + 5 raws each) → ships (a Shipyard). A ship is worth **four weapons of its tier**, in damage and in raw: its recipe is derived from the weapon's raw cost (a T1 ship is 2 construction materials + 1 electronics + 1 fuel = 40 raws = four T1 weapons). A naval war runs in two 24-hour phases. The landing is fought with ships only — $1 + \lfloor L/8 \rfloor$ ships per 40 energy, in whole blocks — so it costs the same per point of damage, in energy and in raw, as a weapon strike, and no building is at risk. If the attackers end the landing strictly ahead, the assault opens, fought with weapons like any war, and the attackers start it with **half** the landing's margin. A tied or lost landing ends the war.

8. REGIONAL INDEXES AND THE CONVOY

Buildings raise five regional indexes (0–10). Health, Education, Military and Industry are a world ranking: every playable region is ranked by its count of Hospitals, Schools, Military Bases plus Missile Systems, or Industrial Zones. The top tenth scores 10, the next tenth 9, and so on; a region without any scores 0. Electricity is local instead: a Power Plant supplies 10, every other building draws 2–6, and a region without a Power Plant has no electricity at all.

The four ranked indexes grant bonuses to anyone standing in the region, all scaled by the electricity index:

$$\text{bonus} = \max \cdot \frac{\text{idx}}{10} \cdot \frac{\text{elec}}{10} \cdot \text{crown}$$

Here **crown** is 1.30, 1.20 or 1.10 in the three cities ranked highest by that day's City Score, and 1 everywhere else. A city's City Score is the average of its five indexes, rounded down, and the cities are ranked every day at 00:00 UTC. Ideology, convoy and Premium are never multiplied by the crown.

INDEX	MAX EFFECT
Health	+50% energy regen
Education	−25% training time
Industry	+25% production
Military	+20% war damage

The **Convoy** is your personal, portable echo of that system: one convoy per player, up to four structures (slots unlock at levels 25, 50 and 100; the fourth slot rides only with an active Premium), each built at a chosen level 1–10 and granting $\text{cap} \times L/10$:

STRUCTURE	SIGNATURE RAW	CAP AT L10
Field Hospital	Cotton	+20% regen
Field Academy	Timber	−10% training
Mobile Workshop	Coal	+10% production
Forward Command	Copper	+8% damage

Construction is a **site project**: the bill (base row × level, touching all seven raws) is delivered from storage in installments; locked materials are non-refundable. A finished structure lives exactly **7 days**, then collapses — no maintenance, no extensions. The convoy travels with you instantly; convoy caps are ~40% of the regional maxima by design, so developed regions and the wars fought over them always matter more.

9. THE STATE LEDGER

Treasuries earn taxes, donations and contract notary fees. They spend on buildings through a building law — voted by parliament, or enacted directly by the Economy Minister. Every building bill is gold plus **all seven raws**. Five buildings carry a thematic signature (~35–47% of the raw bill): a Hospital is cotton-heavy, a School timber-heavy, a Military Base iron-heavy, a Power Plant coal-heavy and a Missile System copper-heavy. The Industrial Zone has no heavy line: its largest, coal, is only ~20%. Either way, one construction project moves seven markets at once.

Closed borders cost the state's stockpile **2 grain and 1 oil per owned region every minute**. When the stock runs dry, the borders open on their own. Office salaries do not touch the treasury: the game mints them.

10. GOLD: FAUCETS AND SINKS

FAUCETS (GOLD IN)	SINKS (GOLD OUT)
Level-ups: $3L$ per level reached	Training: n gold per stat level
Daily reward: 10 (20 with Premium) · missions: up to 40 a day (80 with Premium)	Company founding (100 / 250 / 500) & upgrades ($15n$, uncapped)

FAUCETS (GOLD IN)	SINKS (GOLD OUT)
Office salaries, per owned region per day: President 10, each minister 5, a dictatorship's Leader 20	Energy drinks (1 g = 10 energy)
Achievements: one-time 10–250 gold	Convoy site fees ($5\times$ level)
Weekly press prizes: Newspaper 500, Journalist 250	Party (50), newspaper (5), name change (50), company move (100)
Tutorial/referral one-times	Rebellion (50 per participant, burned)
Real-money shop	Contract notary fees (5–20), frontier levy (burned), state donations

Organic faucets are one-time, trickle-sized or tied to an office; the sinks scale with ambition. Gold holds value because goods cannot glut: a player's output grows only as fast as training time allows, while war, construction, convoy cycles, Resource Plant upgrades and closed borders consume without cap.

11. SIMULATIONS

A. DAY ONE

A new citizen lands with **500 local, 50 gold, 3 food, 3 weapons and 3 tickets** (all T1), stats 0, level 1. Full energy (100) worked in one click at a bare rate of 2 units per block: $\lfloor 100 \cdot 2/10 \rfloor = 20$ units. At a 30-local block wage: gross $30 \times 10 = 300$, minus 10% income tax → **270 local**. First skill training: 1 gold, about a second. The loop is visible in the first minute.

B. AN ESTABLISHED PRODUCER'S DAY

Profile: $S_{eco} = 25$, $E = 20$, $L = 25$; Resource Plant (cotton) level 8 in a +20% cotton region; Industry index 6, electricity 8; no crowding, no pioneer bonus.

$$M_{\text{stat}} = 1 + 0.5 + 0.3 + 0.12 = 1.92$$

unitsPerBlock $= 2 \cdot 1.92 \cdot 1.07 \cdot 1.2 \approx 4.93$; industry $= 1 + 0.25 \cdot 0.6 \cdot 0.8 = 1.12$ → ups $\approx 4.93 \cdot 1.12 \approx 5.52$.

Spending ~600 energy across a day: $\lfloor 600 \cdot 5.52/10 \rfloor =$ **331 cotton**, before the state's production tax takes its share. Sold at 4 local: 1,324 gross, ~1,192 after tax. That cotton is the cotton line of about eleven

state Hospitals (30 each), or of two level-10 Field Hospitals (140 each) with some to spare — one dedicated producer feeds a handful of consumers, never a whole nation.

C. A FIGHTER'S WAR DAY

Profile: $L = 30 (\text{energyMax} = 245)$, $S_{str} = 40$, T3 weapons, Military index 5 / elec 8, Forward Command L5 (+4%).

Blocks: $\lceil 245/10 \rceil = 25$; weapons burned: $25 \times (1 + 3) = \mathbf{100\ T3\ weapons}$.

$$\text{damage} = 100 \cdot 45 \cdot 2.0 \cdot (1.08 + 0.04) = \mathbf{10{,}080}$$

before the roll: the hit lands anywhere from 9,072 to 11,088, or ×1.5 on a critical. XP: $20 \cdot 245/10 = 490$ XP (980 in Golden Hours). At ~96 local per T3 weapon that strike cost ~9,600 local — the iron behind it is **3,500 raw**, several producer-days consumed in one afternoon. War is why goods never rot on the shelves.

D. A CONVOY WEEK

Mobile Workshop L6: bill = base row × 6 → **84 coal, 24 timber, 24 iron, 18 copper, 12 grain, 12 oil, 6 cotton** + 30 gold fee. For 7 days it grants +6% production. Producer B above makes 349 cotton a day instead of 331 — **~18 more a day, ~126 over the week** — comfortably above the bill's market value, but only if he keeps working. Idle convoys are pure loss; active ones compound. That is the economy in one sentence: *Parlamentum pays those who show up.*
